

Comp 322/422 - Software Development for Wireless and Mobile Devices

Fall Semester 2019 - Week 11

Dr Nick Hayward

React JavaScript Library - non-ES6

state - intro - part I

- a component in React is able to house *state*
- *State* is inherently different from *props* because it is internal to the component
- it is particularly useful for deciding a view state on an element
 - *eg: we could use state to track options within a hidden list or menu*
 - *track the current state*
 - *change it relative to component requirements*
 - *then show options based upon this amended state*
- **NB:** considered bad practice to update state directly using `this.state`
 - *use the method `this.setState`*
- try to avoid storing computed values or components directly in *state*
- focus upon using simple data
 - *directly required for given component to function correctly*
- considered good practice to perform required calculations in the *render* function
- try to avoid duplicating *prop* data into *state*
 - *use the `props` data instead*

React JavaScript Library - non-ES6

state - intro - part 2

```
var EditButton = React.createClass({
  getInitialState: function() {
    return {
      editShow: true
    };
  },
  render: function() {
    if (this.state.editShow == false) {
      alert('edit button will be turned off...');
    }
    return (
      <button className="button edit" onClick={this.handleClick}>Edit</button>
    );
  },
  handleClick: function() {
    //handle click...
    alert('edit button clicked');
    //set state after button click
    this.setState({ editShow: false });
  }
});
```

React Native - State

component and constructor

```
// abstracted component for rendering *tape* text
class EditButton extends Component {
  // instantiate object - expects props parameter, e.g. text & value
  constructor(props) {
    // calls parent class' constructor with `props` provided - i.e. uses Component
    super(props);
    // set initial state - e.g. text is shown
    this.state = { editShow: true };
  }
  // custom function to modify state on button click
  handleClick = () => {
    //set state after button click
    this.setState({ editShow: false });
  }
  // component render - check state of component...
  render() {
    if (this.state.editShow == false) {
      return (
        <Text style={styles.content}>
          Button has been removed...
        </Text>
      );
    } else {
      return (
        <View style={styles.buttonBox}>
          <Button
            onPress={this.handleClick}
            title={this.props.title}
            color='#585459'
          />
        </View>
      );
    }
  }
}
```

Image - React Native - Set State

component and constructor

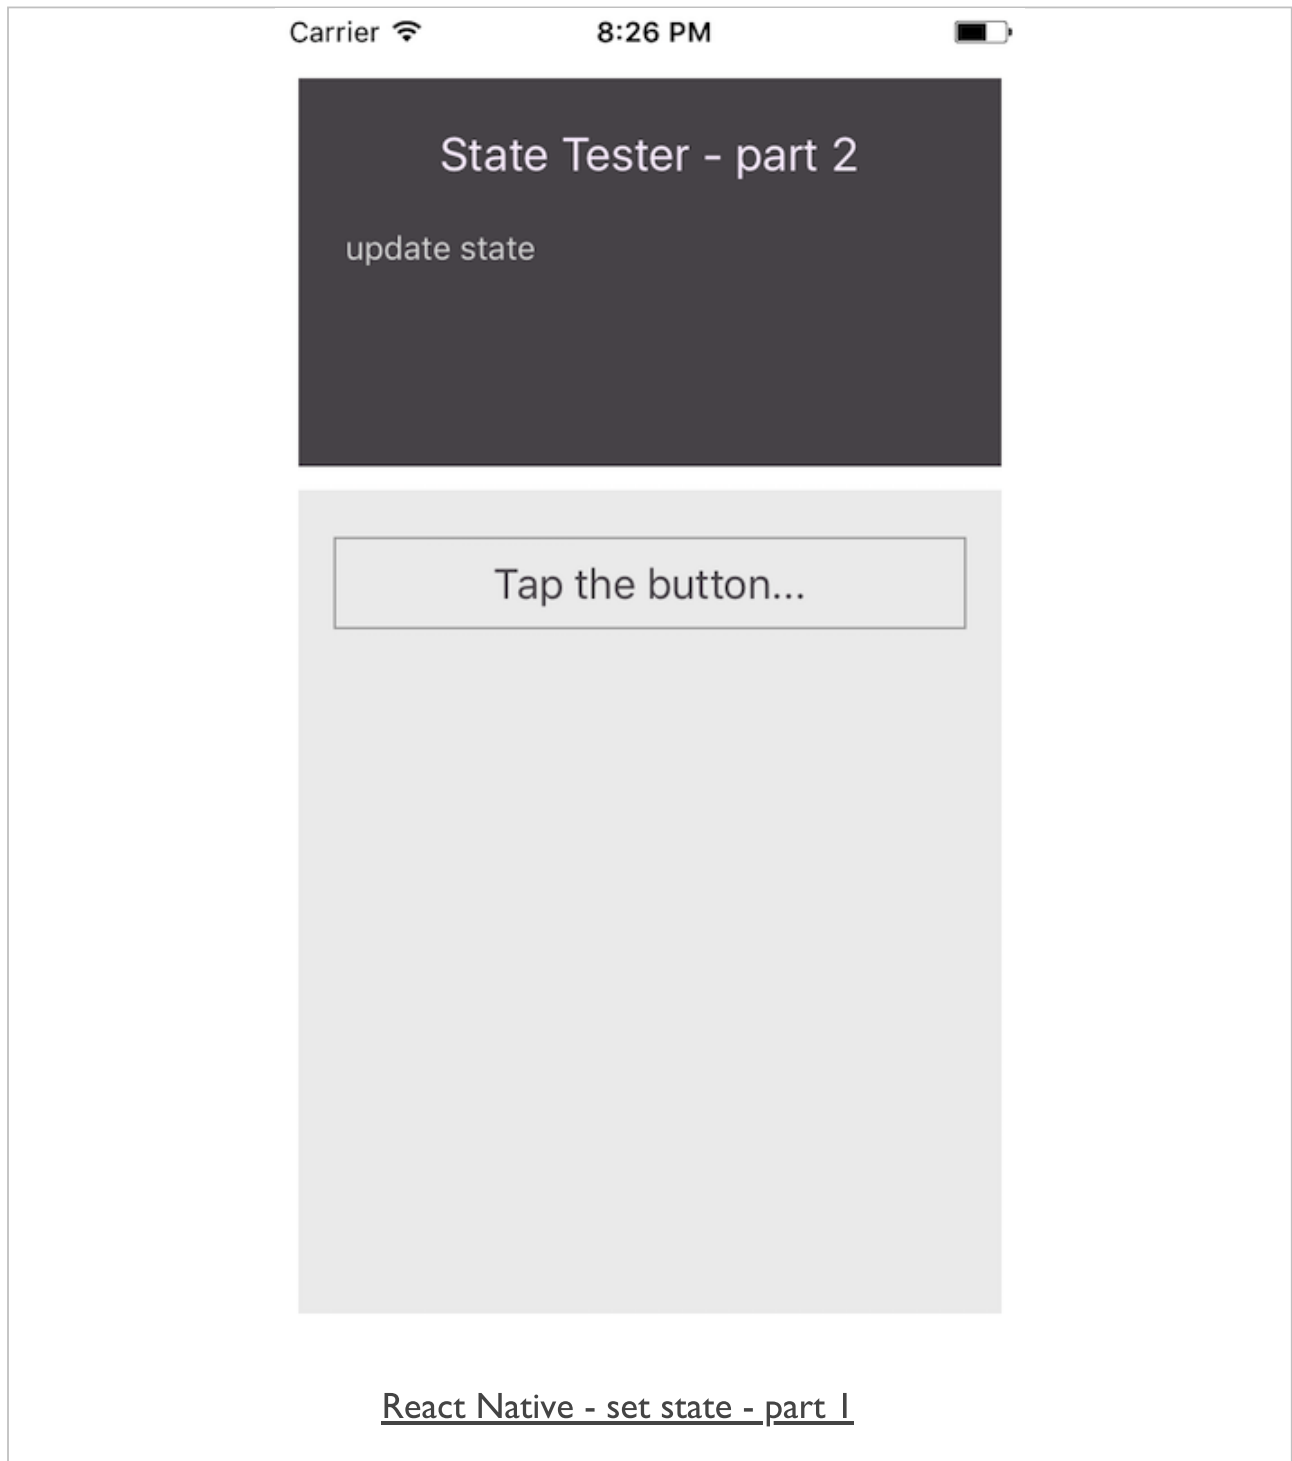

Image - React Native - Set State

component and constructor

React JavaScript Library - non-ES6

state - intro - part 3

- when designing React apps, we often think about
 - **stateless children** and a **stateful parent**

A common pattern is to create several stateless components that just render data, and have a stateful component above them in the hierarchy that passes its state to its children via props.

React documentation

- need to carefully consider how to identify and implement this type of component hierarchy
 1. Stateless child components
 - components should be passed data via *props* from the parent
 - to remain stateless they should not manipulate their *state*
 - they should send a callback to the parent informing it of a change, update etc
 - parent will then decide whether it should result in a *state* change, and a re-rendering of the DOM
 2. Stateful parent component
 - can exist at any level of the hierarchy
 - does not have to be the root component for the app
 - instead can exist as a child to other parents
 - use parent component to pass *props* to its children
 - maintain and update state for the applicable components

React Native - Components

stateful versus presentational

- with React and React Native
 - *compose existing components*
 - *as well as create our own custom components*
- two important concepts and component types in React and React Native
- **stateful**
 - *stateful is a central point in memory*
 - *used to store information about the app or a component's state*
 - *also maintains the ability to modify and update*
- **stateless**
 - *stateless will calculate its internal state*
 - *it should not directly change or mutate this state*
 - *inherent benefit is that we now maintain a clear, transparent record*
 - *given the same inputs, it will always return the same output*

React Native - Components

presentational

- presentational components in a UI
 - *often a reflection of passed or received data*
 - *e.g. a list output of data or some text output for the user to read...*
- React Native UI composed of many smaller blocks
- each block should also be reusable, e.g.

```
class Heading extends Component {  
  render() {  
    return(  
      <View style={styles.headingBox}>  
        <Text style={styles.heading}>  
          { this.props.text }  
        </Text>  
      </View>  
    )  
  }  
}
```

- this component may now be reused for headings in the UI
- component itself does not have any state
- simply a *presentational* or *functional* component
- component is a pure function of props passed from its parent
 - *it does not mutate its arguments*

React Native - Components

presentational and functional

- consider such presentational components from their pure functional context
- rewrite our Heading component as follows,

```
function Heading(props) {  
  return (  
    <View style={styles.headingBox}>  
      <Text style={styles.heading}>  
        { this.props.text }  
      </Text>  
    </View>  
  )  
}
```

React JavaScript Library - non-ES6

state - intro - part 4

1. props vs state

- *in React, we can often consider two types of model data*
- *includes `props` and `state`*
- *most components normally take their data from `props`*
- *allows them to render the required data*
- *as we work with users, add interactivity, and query and respond to servers*
- *we also need to consider the `state` of the application*
- *`state` is very useful and important in React*
- *also important to try and keep many of our components stateless*

2. state

- *React considers user interfaces, UIs, as simple state machines*
- *acting in various states and then rendering as required*
- *in React, we simply update a component's state*
- *then render the new corresponding UI*

React JavaScript Library - non-ES6

state - intro - part 5

I. How state works

- if there is a change in data in the application
 - *perhaps due to a server update or user interaction*
 - *quickly and easily inform React by calling `setState(data, callback)`*
- this method allows us to easily merge data into `this.state`
 - *re-renders the component*
- as re-rendering is finished
 - *optional `callback` is available and is called by React*
- this `callback` will often be unnecessary
 - *it's still useful to know it is available*

React JavaScript Library - non-ES6

state - intro - part 6

2. In state

- try to keep data in state to a minimum
 - *consider minimal possible representation of an application's state*
 - *helps build a stateful component*
- state should try to just contain minimal data
 - *data required by a component's event handlers to help trigger a UI update*
 - *if and when they are modified*
- such properties should also normally only be stored in `this.state`
- as we render the updated UI
 - *simply compute required information in the `render()` method based on this state*
 - *avoids need to keep computed values in sync in state*
 - *instead relying on React to compute them for us*

3. out of state

- in React, `this.state` should only contain minimal data
- minimum necessary to represent an application's UI state
- should contain
 - *computed value/values*
 - *React components*
 - *duplicated data from props*

React JavaScript Library - non-ES6

state - an example app - part I

- a simple app to allow us to test the concept of stateful parent and stateless child components
- resultant app outputs two parallel `div` elements
- allow a user to select one of the available categories
- then view all of the available *authors*

```
//static test data...
var AUTHORS = [
  {id:1, category: 'greek', categoryId:1, author: 'Plato'},
  {id:2, category: 'greek', categoryId:1, author: 'Aristotle'},
  {id:3, category: 'greek', categoryId:1, author: 'Aeschylus'},
  {id:4, category: 'roman', categoryId:2, author: 'Livy'},
  {id:5, category: 'greek', categoryId:1, author: 'Euripides'},
  {id:6, category: 'roman', categoryId:2, author: 'Ptolemy'},
  {id:7, category: 'greek', categoryId:1, author: 'Sophocles'},
  {id:8, category: 'roman', categoryId:2, author: 'Virgil'},
  {id:9, category: 'roman', categoryId:2, author: 'Juvenal'}
];
```

- start with some static data to help populate our app
- `categoryId` used to filter unique categories
 - *again to help get all of our authors per category*

React JavaScript Library - non-ES6

state - an example app - part 2

- for `stateless` child components
 - *need to output a list of filtered, unique categories*
 - *then a list of authors for each selected category*
- first child component is the `CategoryList`
 - *filters and renders our list of unique categories*
 - *`onClick` attribute is included*
 - *state is therefore passed via callback to the `stateful` parent*

React JavaScript Library

state - an example app - part 3

```
//output unique categories from passed data...
var CategoryList = React.createClass({
  render: function() {
    var category = [];
    return (
      <div id="left-titles" className="col-6">
        <ul>
          {this.props.data.map(function(item) {
            if (category.indexOf(item.category) > -1) {
            } else {
              category.push(item.category);
              return (
                <li key={item.id} onClick={this.props.onCategorySelected.bind(null, it
                  {item.category}
                </li>);
              }, this)}
            }
          </ul>
        </div>
      );
    }
  });
```

- the component is accepting props from the parent component
 - *then informing this parent of a required change in state*
 - *change reported via a callback to the `onCategorySelected` method*
 - *does not change `state` itself*
 - *it simply handles the passed data as required for a React app*

React JavaScript Library - non-ES6

state - an example app - part 4

- need to consider our second `stateless` child component
 - *renders the user's chosen authors per category*
 - *user clicks on their chosen category*
 - *a list of applicable authors is output to the right side div*

```
var AuthorList = React.createClass({
  render: function() {
    return (
      <div id="right-titles" className="col-md-6 col-sm-6 col-xs-6">
        <ul>
          {this.props.authors.map(function(item) {
            return (
              <li key={item.id}>{item.author}</li>
            );
          })}
        </ul>
      </div>
    );
  }
});
```

- this component does not set any state
- simply rendering the passed `props` data for viewing

React JavaScript Library - non-ES6

state - an example app - part 5

- to handle updates to the DOM, we need to consider our `stateful` parent
- this component passes the app's data as `props` to the children
- handles the setting and updating of the `state` for app as well
- as noted in the React documentation,

State should contain data that a component's event handler may change to trigger a UI update.

- for this example app
 - *only need to store the `selectedCategoryAuthors` in state*
 - *enables us to update the UI for our app*

React JavaScript Library - non-ES6

state - an example app - part 6

```
var Container = React.createClass({
  getInitialState: function() {
    return {
      selectedCategoryAuthors: this.getCategoryAuthors(this.props.defaultCategory);
    };
  },
  getCategoryAuthors: function(categoryId) {
    var data = this.props.data;
    return data.filter(function(item) {
      return item.categoryId === categoryId;
    });
  },
  render: function() {
    return (
      <div className="container col-md-12 col-sm-12 col-xs-12">
        <CategoryList data={this.props.data} onCategorySelected={this.onCategorySelected}>
        <AuthorList authors={this.state.selectedCategoryAuthors} />
      </div>
    );
  },
  onCategorySelected: function(categoryId) {
    this.setState({
      selectedCategoryAuthors: this.getCategoryAuthors(categoryId)
    });
  }
});
```

React JavaScript Library - non-ES6

state - an example app - part 7

- our `stateful` parent component sets its initial state
 - *including passed data and app's selected category for authors*
- helps set a default state for the app
 - *we can then modify as a user selects their chosen category*
- callback for this user selected category is handled in the `onCategorySelected` method
 - *updates the app's state for the chosen `categoryId`*
 - *then leads to the app re-rendering the DOM for any changes*
- we still have computed data in the app's state
 - *as noted in the React documentation,*

this.state should only contain the minimal amount of data needed to represent your UIs state...

- we should now move our computations to the `render` method of the parent component
 - *then update state accordingly*

React JavaScript Library - non-ES6

state - an example app - part 8

```
var Container = React.createClass({
  getInitialState: function() {
    return {
      selectedCategoryId: this.props.defaultCategoryId
    };
  },
  render: function() {
    var data = this.props.data;
    var selectedCategoryAuthors = data.filter(function(item) {
      return item.categoryId === this.state.selectedCategoryId;
    }, this);
    return (
      <div className="container col-md-12 col-sm-12 col-xs-12">
        <CategoryList data={this.props.data} onCategorySelected={this.onCategoryS
        <AuthorList authors={selectedCategoryAuthors} />
      </div>
    );
  },
  onCategorySelected: function(categoryId) {
    this.setState({selectedCategoryId: categoryId});
  }
});
```

- state is now solely storing the categoryId for our app
- can be modified and the DOM re-rendered correctly

React JavaScript Library - non-ES6

state - an example app - part 9

- we can then load this application
 - *passing data as props to the Container*
 - *data from JSON Authors*

```
var buildLibrary = React.render (  
  <Container data={AUTHORS} defaultCategoryId='1' />,  
  document.getElementById('library')  
);
```

- DEMO - state example

Fun Exercise - State Usage

Watch the following gaming demo,

- Blocks

Then, consider the following relative to **state**

- how is state being used to initially define the application?
- how is state being updated to modify the game?
- how is state being used to keep scores in the game?
- how is state used to define difficulty levels in the game?

React Native - stateful example - part I

- also create a simple example with React Native components
- start with a standard component structure for a stopwatch

```
class Stopwatch extends Component {  
  render() {  
    return (  
      <View>  
        <Text>Stopwatch</Text>  
      </View>  
    )  
  }  
}
```

React Native - Components

stateful example - part 2

- need to define the initial state for this component
- couple of options, including
 - *constructor and class properties*
- e.g. constructor usage,

```
constructor(props) {  
  super(props);  
  this.state = {  
    seconds: 0  
  };  
}
```

React Native - Components

stateful example - part 3

- also create additional getter methods for other stopwatch values, e.g. minutes.

```
get watchMinutes() {  
  return (  
    this.state.seconds / 60  
  )  
}
```

- then reference seconds and minutes in the render function, e.g.

```
render() {  
  return (  
    <View>  
      <Text>Stopwatch: `${this.watchMinutes} : ${this.state.seconds}`</Text>  
    </View>  
  )  
}
```

React Native - Components

stateful example - part 4

- still need to inform React of a change in state
 - *for each second that passes whilst the stopwatch is active*
- the state is immutable
 - *we can only update it by executing the `setState` function*
- in the component, add the following for a second counter for the stopwatch

```
setInterval(() => {  
  this.setState({  
    seconds: this.state.seconds + 1  
  });  
}, 1000);
```

React JavaScript Library

state - minimal state - part I

- to help make our UI interactive
 - *use React's `state` to trigger changes to the underlying data model of an application*
 - *need to keep a minimal set of mutable state*
- **DRY**, or *don't repeat yourself*
 - *often cited as a good rule of thumb for this minimal set*
- need to decide upon an absolute minimal representation of the state of the application
 - *then compute everything else as required*
 - *eg: if we maintain an array of items*
 - *common practice to calculate array length as needed instead of maintaining a counter*

React JavaScript Library

state - minimal state - part 2

- as we develop an application with React
 - *start dividing our data into logical pieces*
 - *then start to consider which is state*
- for example,
 - *is it from props?*
 - *if yes, this is probably not state in React*
 - *does it update or change over time? (eg: due to API updates etc)*
 - *if yes, this is probably not state*
 - *can you compute the data based upon other state or props in a component?*
 - *if yes, it is not state*
- need to decide upon our minimal set of components that mutate, or own state
 - *React is based on the premise of one-way data flow down the hierarchy of components*
 - *can often be quite tricky to determine*
- initially, we can check the following
 - *each component that renders something based on state*
 - *determine the parent component that needs the state in the hierarchy*
 - *a common or parent component should own the state*
 - *NB: if this can't be determined*
 - *simply create a basic component to hold this state*
 - *add component at the top of the state hierarchy*

React Native - Lifecycle methods

mounting

- create stateful components in React and React Native
 - *monitor and use various lifecycle hooks*
 - *in addition to the `setState()` method...*
- start by considering component rendering
 - *better known as **mounting***
 - *various methods to cover each stage of component lifecycle*
- `componentWillMount`
 - *called immediately before component mounting*
 - *not recommended by Facebook's own documentation*
 - *better to use constructor for setting values &c.*
 - *calls to `setState` in this method will not trigger re-rendering*
- `componentDidMount`
 - *called after component mounting*
 - *use this method to initialise timers, any event listeners, fetch data, &c.*
 - *calls to `setState` will trigger re-render*
- `componentWillUnmount`
 - *called just before the component is unmounted and destroyed*
 - *normally use this method for component cleanup &c.*
 - *e.g. removing timers, stopping data requests, API calls &c.*

React Native - Lifecycle methods

updating

- components in React will be updated as and when their state is changed
 - *or if the parent component passes different props*
- we can take advantage of this data flow and pattern
 - *executing any required logic before a component gets updated...*
- React provides methods for such points in a components lifecycle
 - *thereby allowing us to handle updates*
- `componentWillReceiveProps`
 - *useful method to trigger a change in state due to a change in props*
 - *may also use this method to help collate changes in props*
 - *i.e. before and after updates, e.g.*

```
...
componentWillReceiveProps(updatedProps) {
  if (updatedProps !== this.props) {
    ...
  }
}
```

- `shouldComponentUpdate`
 - *React will usually re-render a component for each change in state*
 - *this method allows us to specify whether a component should update, how, &c.*
 - *e.g. re-render a component only for a specific update*
 - *return `false` from this method - a component will not be re-rendered*

React Native - Platform Structure

cross-platform

- React Native gives us a default directory and script structure
 - *part of the structure for a newly initialised app*
- modify structure as app grows in complexity and scope
- React Native provides app initialisation files
 - *index.js & App.js*
- create a custom directory for app, e.g.
 - *src or app &c.*
 - *add directories for UI components, assets, scripts for APIs...*
- import `App.js` from `src &c.` directory

```
import App from './src/App';
```

React Native - Platform Structure

Android & iOS

- then start to add platform specific requirements
 - *including components, styles, images...*
- customisation is being encouraged with the Platform component. e.g.

```
import { Platform } from 'react-native';
```

- add checks to the logic of our app to add platform specific customisations,

```
const titles = Platform.select({  
  ios: 'iOS custom title...',  
  android: 'Android custom title...',  
});
```

- to use this in our app's code
 - *do not need to specify iOS or Android*
 - *simply add the required output for titles. e.g.*

```
...  
<View>  
  <Text>{titles}</Text>  
</View>  
...
```

React Native - component usage

StatusBar

- add customisation to our app's *Status Bar*
 - *top bar with network icon, data, battery status, notification icons &c*
- various customisation options for each platform
 - *animate this bar*
 - *modify its colour*
 - *add custom style to match the current mode or status within our app*
- simple modification is to update the background colour
 - *from light to dark, and vice versa...*
 - *e.g. inform user of status change by animating the colour change and update*
- need to import the *StatusBar* component
 - *add an `animated` prop for the component*
 - *and specify a `barStyle` for the bar itself*
- e.g. set the background colour of the bar to white

```
<StatusBar animated barStyle="light-content" />
```

- we might also set the `barStyle` to dark using the value `dark-content`
 - *sets colour of status bar text*
- we can only use the `barStyle` prop with iOS
- for Android, we can set props for `backgroundColor` and `translucent`
- additional options for working with the *StatusBar*, including static functions
 - *StatusBar*

Image - React Native - Component Usage

StatusBar

React Native - StatusBar

React Native - component usage

images

- use Image component to add images
 - *and various static resources as well*
- Image component works with local and remote sources
 - *able to fetch remote images from a specified URL or server address*

```
...  
<Image  
  style={styles.image}  
  resizeMode="contain"  
  source={{  
    uri: 'http://www.test.com/images/image.png'  
  }}  
</>  
...
```

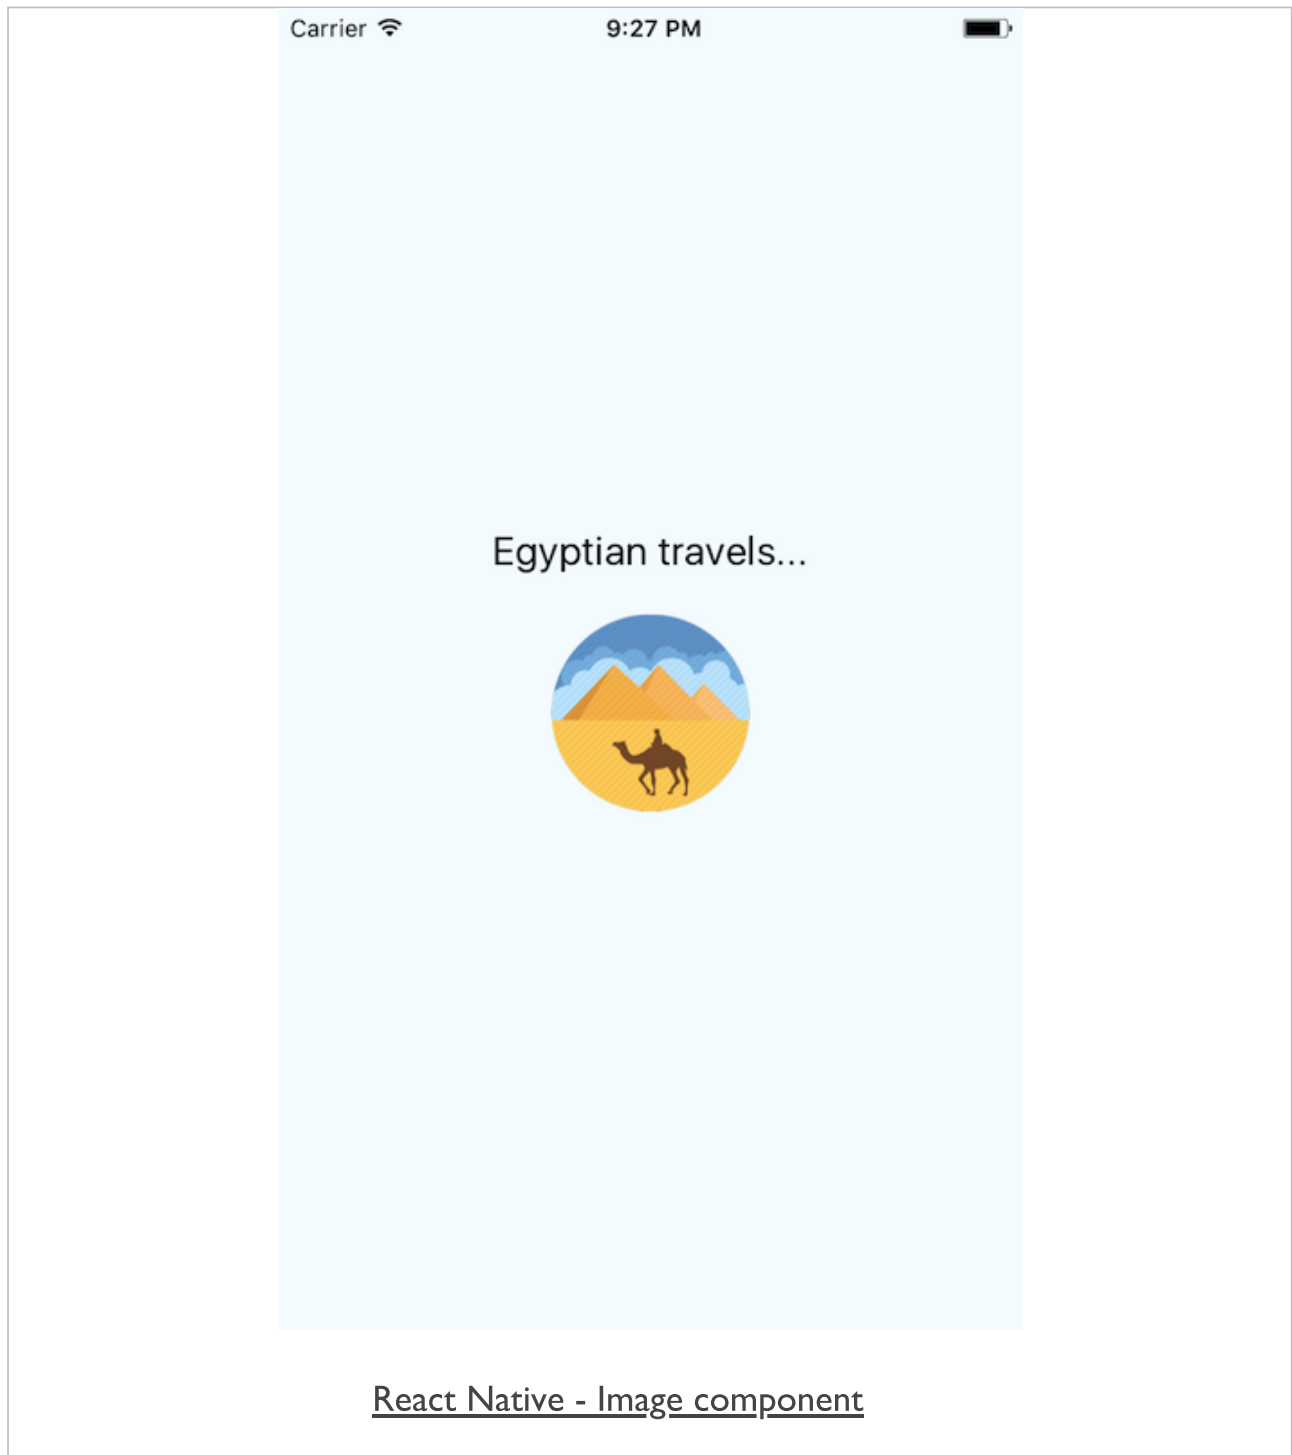

or

```
<Image  
  style={styles.image}  
  resizeMode="contain"  
  source={require('./images/camel-icon.png')}  
</>
```

- resizeMode prop may accept various values to help with layout and design
 - *cover, contain, stretch, repeat (only iOS), center*
- also check and use additional lifecycle props with images, including
 - *onLoad*
 - *onLoadEnd*
 - *onLoadStart*
- also get the size of a specified image before rendering it to the View

Image - React Native - Component Usage

Image component

React Native - component usage

activity indicator

- `ActivityIndicator` component gives us a default spinning loader for an app
 - *a small default component*
 - *useful for async loading, animations...*
- in addition to standard `View` props - also accepts the following
 - *animating* - boolean value to determine whether to spin or not
 - *color* - specify the foreground colour of the spinner
 - *size* - pass *small* or *large* string for iOS, and a size value for Android

React Native - component usage

activity indicator - example

- might want to use the `ActivityIndicator` to delay showing an image
- add a property to *state* - use as a simple boolean check for loading of the image
- initial *state* set as follows,

```
state = {  
  showImage: false,  
  loading: false  
}
```

- image is not shown by default
 - *and the `ActivityIndicator` is not visible or active either*
- create a function to allow us to update the state
 - *will show the activity indicator and image*
- we're using ES6 classes for these examples
 - *need to start binding our functions as we pass them as props*
 - e.g.

```
// instantiate object  
constructor(props) {  
  super(props);  
  // bind function  
  this.showImage = this.showImage.bind(this);  
}
```

- `showImage` function can now be added

```
showImage() {  
  this.setState({  
    loading: true  
  });  
  setTimeout(() => {  
    this.setState({  
      showImage: true,  

```

```
    loading: false
  })
}, 2500)
}
```

Image - React Native - Component Usage

ActivityIndicator component - part I

Image - React Native - Component Usage

ActivityIndicator component - part 2

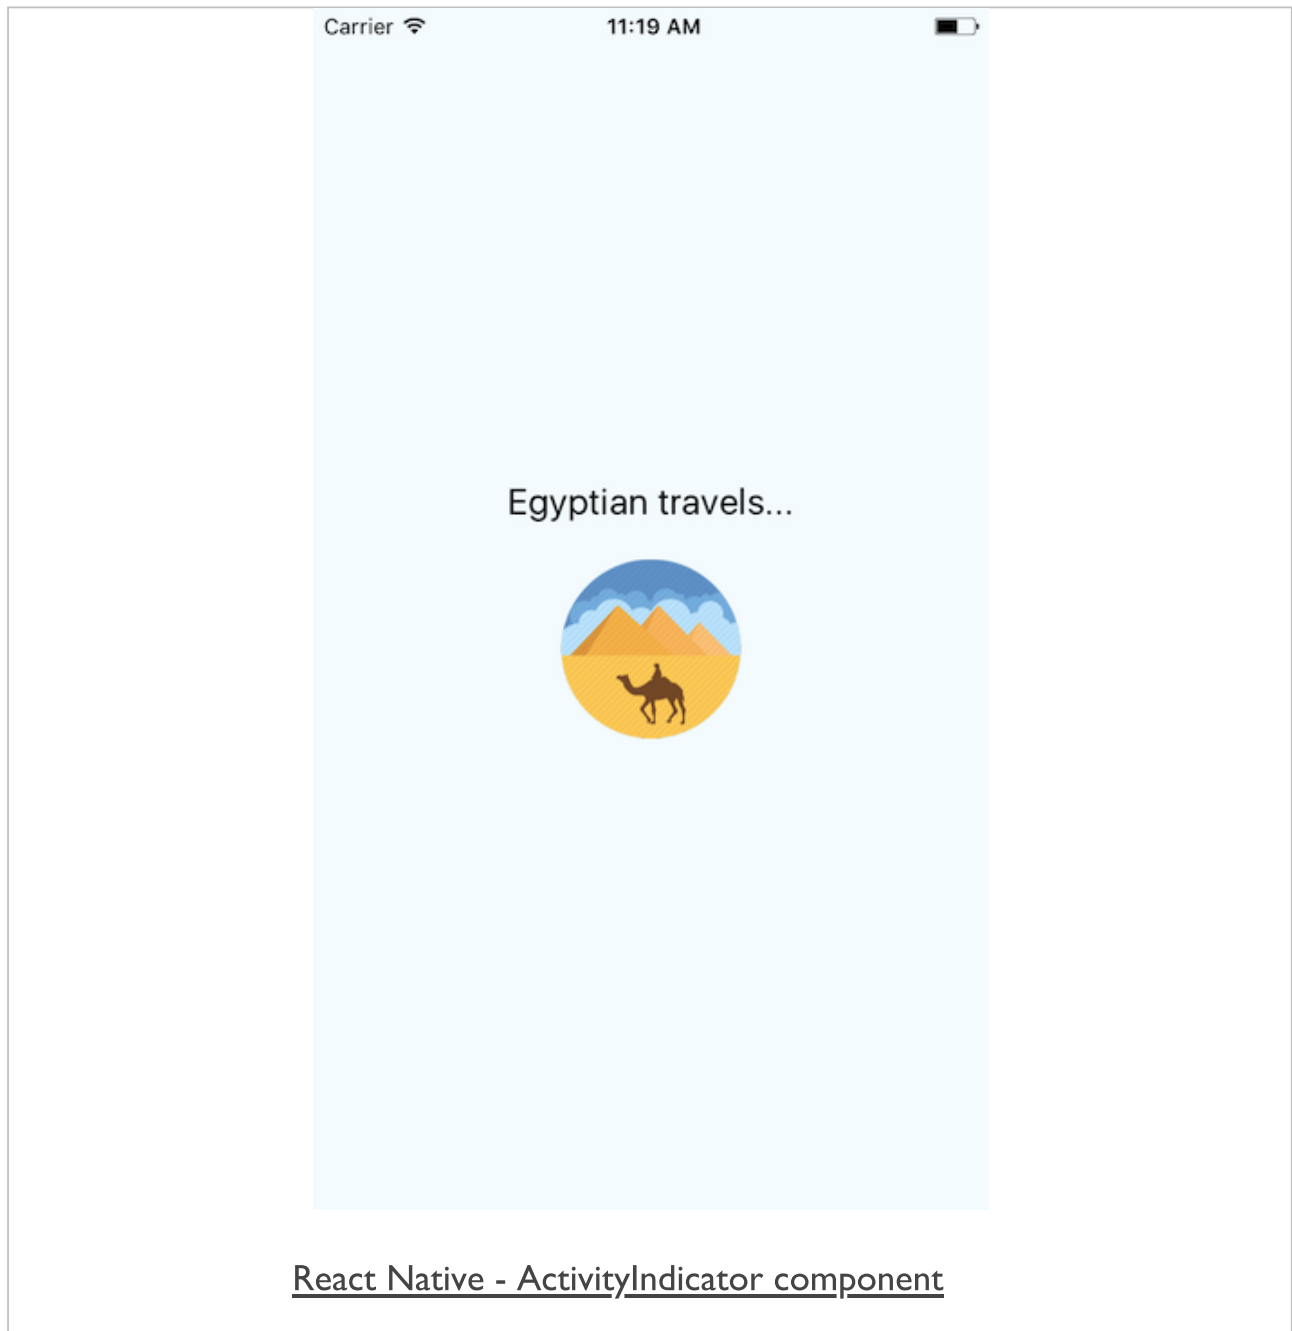

Image - React Native - Component Usage

ActivityIndicator component - part 3

React Native - component usage

custom modal

- React Native also supports a `Modal` component by default
- use it for success messages, feedback or prompts to a user, &c.
- also nest various child components to create the necessary output
- `Modal` component will accept the following props
 - *animationType*
 - *Transparent*
 - *Visible*
 - *onShow*
- also some custom props for each mobile platform
 - e.g. *presentationStyle* for iOS

React Native - component usage

custom modal - example

```
...
state = {
  modalVisible: true,
}

setModalVisible(visible) {
  this.setState({modalVisible: visible});
}

<Modal
  animationType="slide"
  transparent={false}
  visible={this.state.modalVisible}
>
  <View style={styles.modal}>
    <TouchableHighlight onPress={() => {
      this.setModalVisible(!this.state.modalVisible)
    }}>
      <Text style={styles.modalClose}>close</Text>
    </TouchableHighlight>
    <Text style={styles.modalText}>Greetings from Egypt</Text>
  </View>
</Modal>
```

Image - React Native - Component Usage

custom modal component - part I

Mobile Design & Development - UI Components & Usage

Fun Exercise

Four groups, two apps

- Fashion -
<http://linode4.cs.luc.edu/teaching/cs/demos/422/gifs/fashion/>
- Travel Notes -
<http://linode4.cs.luc.edu/teaching/cs/demos/422/videos/travelnotes/>

For each app, consider the following

- define UI components for the app?
- which components may be reused to create different effects?
- which components could be abstracted to extend a parent component?
- how is the UI influenced by the use of such components?

~ 10 minutes
